1 Introduction

1.1 Scope and Purpose

This document contains the interface specifications of the 3D Displays as developed by Philips 3D Solutions. This document covers the physical specification as well as the data format.

All displays with type numbers 42-3D#### and 20-3D#### developed by 3D Solutions comply with the specification described herein.

The header described in section 6 is only supported by displays with firmware 10.7 or higher. Please check your firmware version using the Display Control Tool provided with each Philips 3D display.

The intended audiences are:

- 3D system integrators that do not make use of software from Philips 3D Solutions. The intended applications are 3D CAD design, gaming, gambling, interactive applications, etc. For these persons the sections 6.1 general header location and 6.2 header description are most interesting.
- For the development of digital signage related software we refer to section 6.1 where the general header location is denoted and to section 6.3 where the standard headers are mentioned for the 3d content using the s3d, v3d or b3d extensions.
- For the development of other software, please first contact Philips 3D Solutions.

WOWvx Declipse is only supported on Displays with firmware 10.3 or higher. Please check your firmware version using the DisplayControlTool.

Philips is under no circumstances responsible for malfunctioning of third party software. Furthermore, Philips is not liable for the consequences resulting from changes of mistakes within this whitepaper.

1.3 Notations

0xNN	Hexadecimal numbers are represented by using 'C' language notation.
0bNN	Binary numbers are represented by using 'C' language notation.
NN	Decimal numbers have no prefix.

2 Physical interface

The connection between the host and the 3D Display makes use of a DVI based interface, see [DVI].

Table 1. DVI specifications for the 42" displays

Parameter	Value
Resolution	1920 x 1080
Refresh rate	60 fps
Gamma	No gamma correction.
Reference white	Wx: 0.280 Wy: 0.285 (at 10500°K)
Aspect ratio	16:9
Order of sample scanning	Left to right. Top to bottom. Progressive
Coded signal colour space	RGB (8 bit coding)
Supported standards	[DDC], [DDC/CI]
Not supported standards	[GTF], [DPMS]

Table 2. DVI specifications for the 20" displays

Parameter	Value
Resolution	1600 x 1200
Refresh rate	60 fps
Gamma	No gamma correction.
Reference white	Wx: 0.313 Wy: 0.329 (at 6500°K)
Aspect ratio	4:3
Order of sample scanning	Left to right. Top to bottom. Progressive
Coded signal colour space	RGB (8 bit coding)
Supported standards	[DDC], [DDC/CI]
Not supported standards	[GTF], [DPMS]

3 Display Control Tool

The Display Control Tool is supplied with each 3D Display from Philips 3D Solutions and is running on Windows based computers. It enables the viewer to control the perceived depth and color settings real-time. It is advised to always install the Display Control Tool on each computer.

The Display Control Tool communicates with the display via the DVI cable making use of the [DDC/CI] protocol. There is no interaction on the computer between the Display Control Tool and any other software. So while developing software according to these interface specifications no consideration regarding the Display Control Tool must be taken.

The Display Control Tool requires an NVIDIA graphics card.

See [DCT] for more information about the Display Control Tool.

4 3D Frame

The resolution of a frame that is sent to the display via the DVI cable has a resolution of 1920x1080 for 42" or 1600x1200 for 20". A frame contains the following data:

- 2D sub-image with a resolution 960x540 for 42" or 800x600 for 20"
- Z sub-image with a resolution 960x540 for 42" or 800x600 for 20"
- Header

From now on we continue only with the explanation of 42" (1920x540=2 images of 960x540) The reader interested in 20" display has to read 1600x600= 2 images of 800x600. The rest is stays the same.

This is a very flexible format. Among the advantages of using 2D and Z images (compared to for example 9 separate views) are:

- user control over the amount of perceived depth (controlled via for example the header or via the Display Control Tool)
- (future) compatibility with displays which have a different number of views than the current 9, or have a different lens design which requires different interleaving (see Section 7.2), allowing the display to render in a way optimized for its optical components.
- suitability for compression for content storage and distribution
- advantages in content editing, because the disparity is explicit

More information can be found in [3DTV]. Note: that whenever 2D and Z is mentioned the Z map describes the disparity and not the depth. The picture below shows how the header and the 2D and Z sub-images are organized in a frame of 1920x1080.

Figure 1. Overview of 3D frame.

The 2D and Z sub-images of 960x540 are positioned besides each other, which result in a total line width of 1920 pixels. Between each video line a blank line is added. This doubles the vertical resolution from 540 to 1080. Chapter 5 explains the 2D and Z sub-images in more detail.

A header is located in the upper left corner. The function of the header is twofold. When the display detects the header it switches to 3D mode and the header contains settings for rendering processing. The header is further explained in chapter 6.

5 Video data

5.1 2D and Z sub-images

Figure 2. 3D frame layout.

The picture above shows the layout of a 3D frame. It contains a 2D sub-image and a Z sub-image both with a resolution of 960x540¹. The 2D sub-image is positioned in the left half of the frame, and Z sub-image in the right. A blank line is inserted below each line of the 2D and Z.

5.2 2D sub-image

Properties of 2D sub-image:

- The 2D sub-image has a resolution of 960x540.
- The 2D image is an R,G and B image with 8 bits per sub-pixel.
- No gamma correction is performed in the display.

¹ Like in chapter 4, the resolutions are for the 42" display. You should read 1600x1200 instead of 1920x1080 and 800x600 instead of 960x540 for the 20" display.

Figure 3. 2D sub-image example

5.3 Z image

A Z image contains disparity values with a range of 0 to 255, where a value of 0 corresponds with objects located with a maximum disparity behind the screen and 255 corresponds with objects located closest to the observer.

An implementation is that the Z image is a black and white image. This means that the R, G and B sub-pixels have the same value per pixel. However the display only uses the red sub-pixels. The green and blue sub-pixels are discarded.

Sometimes a Z image is also called 'depth map', but note that it describes the **disparity**.

Figure 4. Z sub-image example

6 Header

The header described in this section is only supported by displays with firmware 10.7 or higher. Please check your firmware version using the Display Control Tool provided with each Philips 3D display. The header is positioned in the upper left corner of a frame. Each frame will contain a header otherwise the display will interpret it as a 2D frame. The header instructs the display which viewing experience is required.

6.1 Header location in the 3D frame

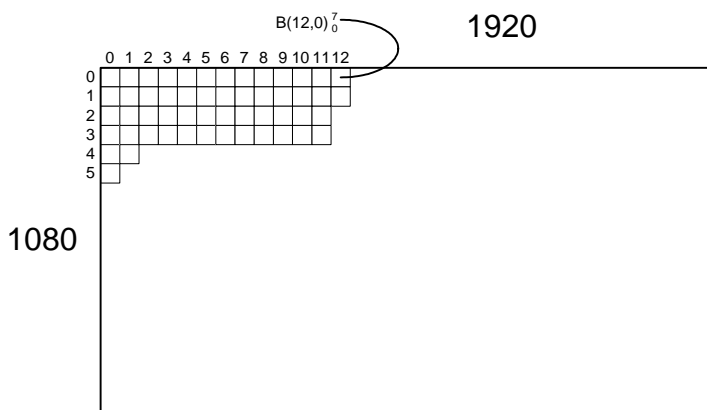

Figure 5. Numbering of rows and columns of screen.

The figure above shows how the columns and rows are numbered. Numbering starts with zero in the upper left corner. Each square pixel consists out of an R, G and B sub-pixel.

$B(12,0)_0^7$ Denotes the blue byte in the upper row in the 13th column and bits 7 down to 0. With 7 the Most Significant Bit.

The header is located in the blue sub-pixels. It is required to give all the 8 bits in the blue sub-pixel the value of the header bit. In this way the system becomes more tolerant to changes in brightness, contrast settings and noise. The header starts at the first pixel in the first row ($B(0,0)$) and onwards ($B(x,0)$). Only in the even blue sub-pixels the header is located, starting with 0, 2, 4 etc.

During rendering, the blue sub-pixels that contain the header are replaced by the blue component of their neighboring pixels. This masks the header entirely, while it hardly affects image quality.

The following formula shows which bit of which sub-pixel byte forms which bit (y) and byte (x) of the header ($x \in [0,30]$, $y \in [0,7]$):

$$B(2 \cdot (7 - y) + 16 \cdot x, 0)^7 = H(x)^y \quad [1]$$

The following translation table shows how the header is composed from bits in the blue sub-pixels. The first header byte, $H(0)$, is composed by combining MSB bits of blue sub-pixels.

Table 3. Translation table of blue sub-pixel MSB bits into header bytes.

Sub-pixel bit	Header bit
$B(0,0)^7$	$H(0)^7$
$B(2,0)^7$	$H(0)^6$
$B(4,0)^7$	$H(0)^5$
$B(6,0)^7$	$H(0)^4$
$B(8,0)^7$	$H(0)^3$
$B(10,0)^7$	$H(0)^2$
$B(12,0)^7$	$H(0)^1$
$B(14,0)^7$	$H(0)^0$
$B(16,0)^7$	$H(1)^7$
$B(18,0)^7$	$H(1)^6$
$B(20,0)^7$	$H(1)^5$
$B(22,0)^7$	$H(1)^4$
$B(24,0)^7$	$H(1)^3$
$B(26,0)^7$	$H(1)^2$
$B(28,0)^7$	$H(1)^1$
$B(30,0)^7$	$H(1)^0$
$B(32,0)^7$	$H(2)^7$
$B(34,0)^7$	$H(2)^6$
$B(36,0)^7$	$H(2)^5$
etc.	etc.

6.2 Header data

The header is 32 bytes long and consists of two main parts: the first part of 10 bytes and the second part of 22 bytes. The table below lists the content of these 32 bytes. The right column contains the actual value or the parameter, which is further defined in sections 6.2.1 to 0.

Byte	Content
$H(0)$	Header_ID1
$H(1)$	Hdr_Content_type
$H(2)$	Hdr_Factor
$H(3)$	Hdr_Offset_CC
$H(4)_6^7$	Hdr_Select_I
$H(4)_5^5, H(5)$	Reserved
$H(6) - H(9)$	EDC_1
$H(10)$	Header_ID2
$H(11) - H(12)$	Data_types
$H(13)_4^7$	Fixed
$H(13)_3^3$	Fixed
$H(13)_0^2$	Reserved
$H(14)$	Reserved
$H(15), H(16), H(17)$	Reserved
$H(18)_6^7$	Fixed
$H(18)_5^5 - H(27)$	Reserved
$H(28) - H(31)$	EDC_2

Unused and reserved bits **must** be set to zero.

The display interprets the header each frame, 60 times per second. Changed header values are effectuated directly.

6.2.1 Header_ID1

Indicates the format of the remainder of the header see table 4.

Table 4 Header_IDs

Byte	Content	Description	Value
$H(0)$	Header_ID1	This header ID indicates the generic header type with a length of 10 bytes as described in 6.2.	11110001

6.2.2 Hdr_Content_type

This value defines the kind of content. Based on this the various visualization parameters, like factor and offset, are chosen that influence the rendering process.

Table 5 Content type

Byte	Content	Type value (7:0)	Type of Content
H(1)	Hdr_Content_type	00000000	No depth
		00000001	Signage
		00000010	Movie
		00000011	Game
		00000100	CGI
		00000101	Still
		00000110	Reserved
		etc.	

6.2.3 Hdr_Factor

Table 6 Header factor value

Byte	Content	Description	Default	Range
H(2)	Factor	Percentage of the display recommended depth value. (Factor/64)	64	[0-255]

Each 3D Display has a 'Display recommended depth value', which corresponds to an acceptable maximum depth factor value for that specific type of display. This value strongly depends on the lens design. The factor field in the header contains the percentage to be used from the display recommended depth value. The value of 64 corresponds with the 100% of the display recommended depth value. It is allowed to use values higher than 64. The factor works on a linear scale and is multiplied with the factor controlled by the user in the Display Control Tool.

6.2.4 Hdr_Offset_CC

Table 7 Header offset value

Byte	Content	Description	Default	Range
H(3)	Offset	Amount of range behind the screen. 0: Range is shifted in the direction of the viewer. 128: Range is equally divided in front and behind the screen. 255: Range is shifted away from the viewer.	128	[0,255]

Values in the Z map equal to the header-offset value will be located on the plane of the display. All values in the disparity map with a higher value will be displayed in front of the display.

Offset_CC is the offset controlled by the Content Creator. In the system there is also an Offset_user present, which is controlled by the user using the Display Control Tool.

6.2.5 Hdr_Select_I

Table 8 Header select

Byte	Content	Description
$H(4)^7$	Hdr_Factor_select	'1': Hdr_Factor is used; '0': Hdr_content_type is used;
$H(4)^6$	Hdr_Offset_CC_select	'1': Hdr_Offset_CC is used; '0': Hdr_content_type is used;

When all select signals are low the rendering settings are set to optimal settings for the content type denoted by Hdr_content_type. By making select signals high the settings for Factor and Offset_cc can be controlled individually by the header.

6.2.6 Reserved

These bits are reserved for future use and should be set to 0 to maintain compatibility with future systems.

6.2.7 EDC_I

The 4-byte EDC field contains an Error Detection Code computed over the first 6 header bytes. This EDC uses the standard CRC-32 polynomial as defined in IEEE 802.3 and ITU-T V.42. The initial value and final XOR value are both 0. An implementation of this algorithm can be found in appendix A.

6.2.8 Header_ID2

Indicates the format of the remainder of the header see table 4.

Table 9 Header_IDs

Byte	Content	Description	Value
$H(10)$	Header_ID2	This header_ID indicates the second WOWvx header type with a length of 22 bytes as described in 6.2.	11110010

6.2.9 Data_types

One image can contain up to 4 sub-images. Data_types describes the contents of the 4 sub-pictures as described in table 10. The sub-images are named A, B, C and D, figure 6 shows how the images A, B, C and D are arranged on the interface.

Figure 6. Naming order of the 4 images.

Table 10. Data type of the supporting render methods

Byte	Content	Description	Value
$H(11)$ $H(12)$	Data_type	The 'traditional' 2D+Z format as denoted below	00010100 00000000
$H(11)$ $H(12)$	Data_type	The 2D+Z and background picture as denoted below	10111100 00010100

Using the above information we show two supported image formats. The images are displayed as present in the video files. When they are on the interface they are interleaved as shown in figure 6 (Location).

'Traditional' 2D +Z

Data_type = "00010100 00000000"

Location	Description	Reference to image
A	2D	left
B	Depth	right
C	empty	-
D	empty	-

'Removed redundant data'

This is the default version especially designed for content that is being stored in compressed form.

Data_type = "00010100 10011010"

Location	Description	Reference to image
A	2D	top-left
B	Depth	top-right
C	2D Background	bottom left
D	Depth Background	bottom-right

'2D+Z' + Background picture

The following is specifically used for uncompressed data (as in applications that generate content).

Data_type = "00010100 11101111"

Location	Description	Reference to image
A	2D	top-left
B	Depth	top-right
C	2D Background	bottom left
D	Depth Background	bottom-right

6.2.10 Fixed H(13)

Table 11 Fixed values

Byte	Fixed
$H(13)_6^7$	01
$H(13)_4^5$	01
$H(13)^3$	0

6.2.11 Reserved

$H(13)_0^2, H(14), H(15), H(16), H(17)$: these bits are reserved for future use and should be set to 0 to maintain compatibility with future systems.

6.2.12 Fixed H(18)

Table 12 Fixed values

Byte	Fixed
$H(18)^7$	0
$H(18)^6$	0

6.2.13 EDC_2

The 4-byte EDC field contains an Error Detection Code computed over the first 18 bytes of the second header. This EDC uses the standard CRC-32 polynomial as defined in IEEE 802.3 and ITU-T V.42. The initial value and final XOR value are both 0. An implementation of this algorithm can be found in appendix A.

6.3 Content

In many applications a standard header is sufficient. E.g. for our *.v3d, *.s3d and *.b3d files the 3dsmediaplayer uses a standard header (as denoted in table 13), that can be very easily applied.

Table 13 Standard headers

Extension	Header	Description
s3d	F10140800000C42DD3AF	Used for signage content.
v3d	F102408000001F3A7B38	Used for video content.
b3d	F10540800000E4D9502C	Used for stills.

We refer to section 6.1 for more information on the location of the header and how to code it into the image.

7 Operation modes

The display has two operational modes, i.e. 2D mode and 3D mode, which are described in sections 7.1 and 7.2 respectively.

7.1 2D Mode

At the moment that the display detects no header it switches back to 2D mode. The 2D mode is achieved by placing the 1920x1080 pixels on the display after a image processing step that lowers the visibility of the optical coupling between the LCD and the lens layer. Thereby a high quality 2D image is visualized.

7.2 3D Mode

The image processing within the display takes place in 3 steps, see Figure 7.

First a frame with a header and a 2D and Z sub-image is applied to the DVI input connector. A demultiplexing block decomposes the 3D frame into the header and the 2D and Z sub-images. These 3 components are applied to the rendering block.

The rendering block generates 9 images, which have all a slightly different camera positions. The amount of perceived depth and other depth related parameters are controlled by the values in the header.

The 9 different images are fed to the interweaving block. This block ensures that each sub-pixel is exactly located under the right lens, which ensures the best 3D experience. The interweaving process is optimized for the optical behavior of the lens layer.

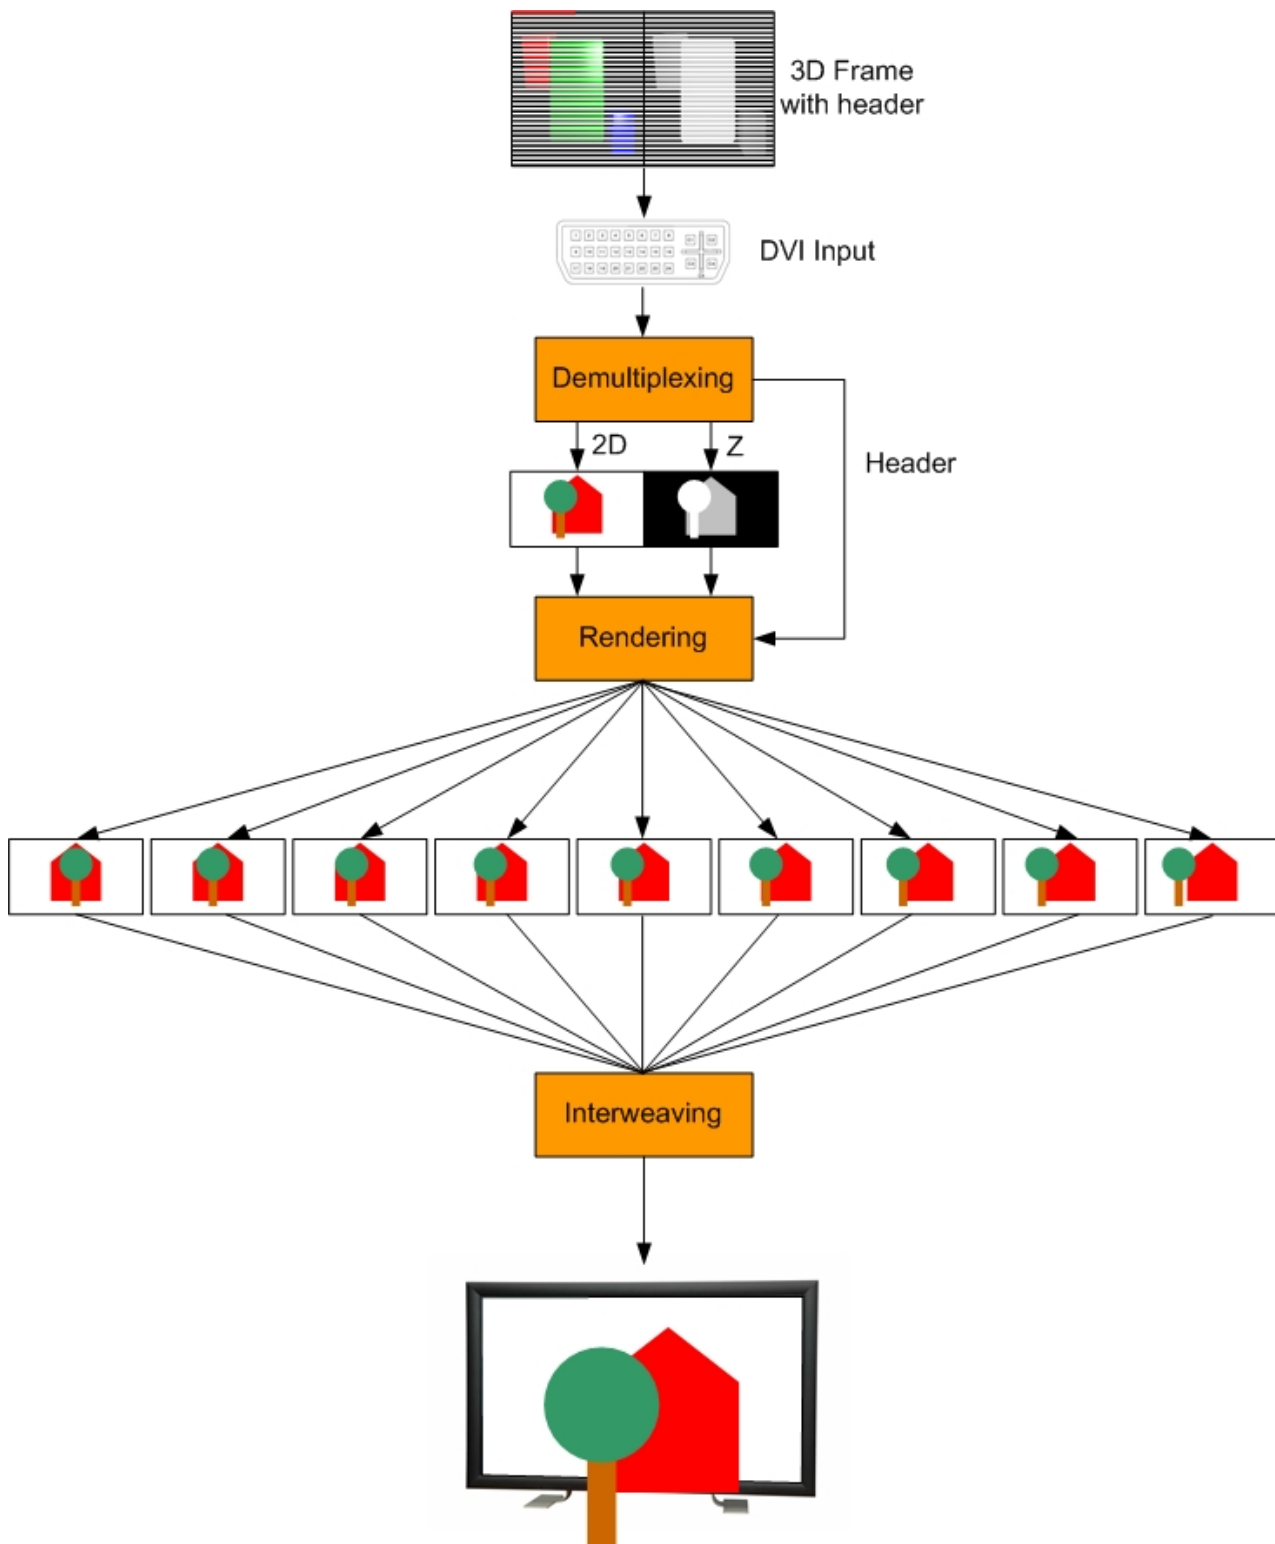

Figure 7. Overview of 3D image processing in the display.

8 Stretching of images

If an object positioned at the left edge of the image has a depth that puts it behind the screen, a viewer looking at it from the right would expect to see more pixels to the left of the object where the frame of the display would no longer be concealing the object. Because these pixels are not in the original image, the image is stretched slightly before rendering to prevent this problem. Figure 8 shows how the image is stretched.

Stretching and rendering takes place inside the display.

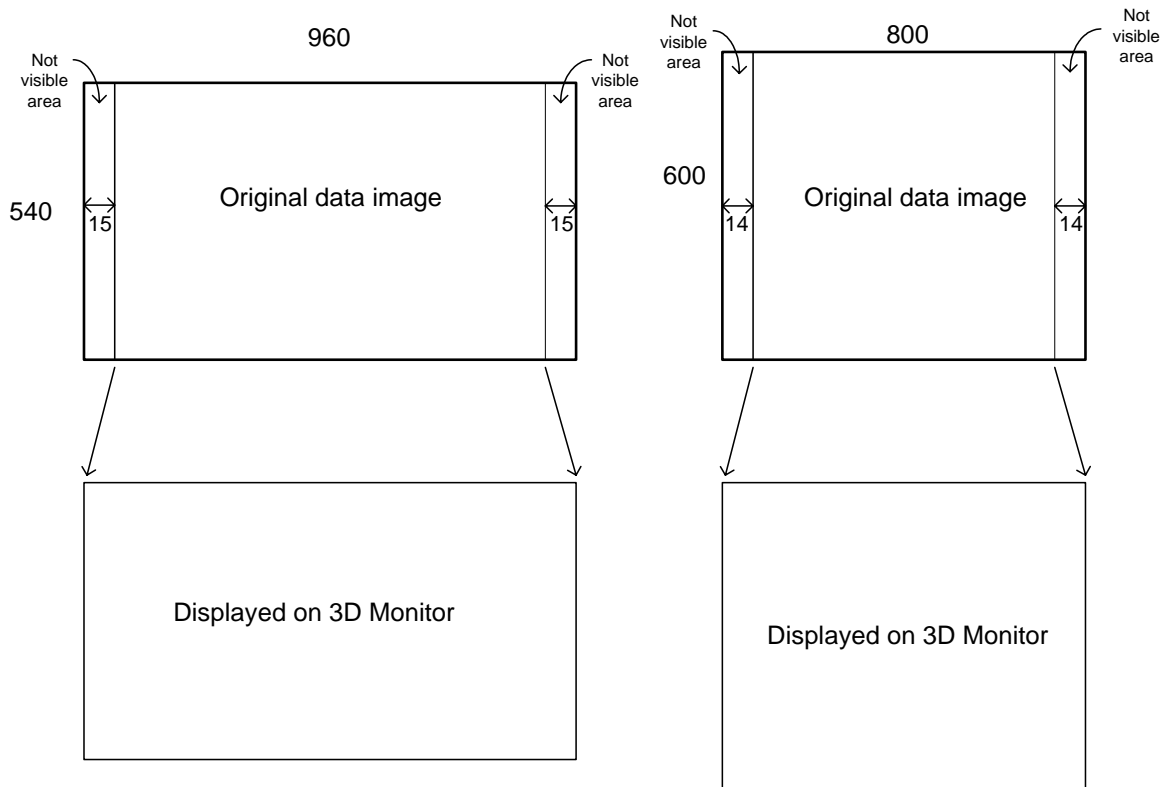

Figure 8. A band at the left and right side of the image data are not displayed on the 3D Display.

The original 2D input data has a resolution of 960x540. The leftmost pixels and the rightmost pixels of each row are not visible on the display, when the depth of the pixels is on the screen. However when the depth is behind the screen, the observer is able to see this information in these bands.

So while sending content to the display the designer must keep in mind that small bands at the left and right side will mostly not be visible. This holds especially for text and logos that are closely located to left and right borders of the screen.

A side effect of this stretching is that the aspect ratio of the content is somewhat distorted.

Table 14 Sizes of the "invisible" borders

Display	Pixels on the left	Pixels on the right
42" display, firmware version > 9.6	10	10
20" display, firmware version > 8.0	8	8

9 Converting depth to disparity

In 3D application a 3 dimensional (Cartesian) coordinate system is used to model objects. Normally these models are used to generate 2D images of scenes like: games or other applications. The function below describes the translation from depth (Z) to disparity ($D(Z)$). Herein depth describes the depth extracted from the application and needs to be normalized between 0 and 1. Further disparity refers to the difference in images from the left and right eye that the brain uses as a binocular cue to determine depth or distance of an object. The function below will describe the correct translation between depth and disparity:

$$D(Z) = M * \left(1 - \frac{vz}{Z - Zd + vz} \right) + C$$

where:

D : disparity [0,255]

Z : depth [0,1]

M : Linear function multiplier

Zd : depth of display plane

vz : View distance in coordinate units

C : Linear function constant

Within this formula there are a number of constants present M , Zd , vz and C . To obtain the best 3D performance for each of our displays use the correct values from the table below:

Constant	42"	20"
Zd	0.467481	0.459813
vz	7.655192	6.180772
M	-1960.37	-1586.34
C	127.5	127.5

There are two kinds of 42" displays WOW and Comfort; both displays use the same constants within the conversion function.

/*                               End of CRC Lookup Table                               */
/*****

/* Calculate CRC-32 Checksum

Uses reflected table driven method documented by Ross Williams.

PARAMETERS:

```

```
unsigned char *p          Buffer containing data over which
                          to calculate the CRC
unsigned long len         Length of data in the buffer
```

```
RETURNS:
checksum value
```

```
Author:
Eric Durbin              1998-10-14
```
